## 1 globus rls client Main Page

There are 2 types of RLS servers, Local Replica Catalog (LRC) servers, which maintain Logical to Physical File Name mappings (LFN to PFN), and Replica Location Index (RLI) servers, which maintain LFN to LRC mappings. Note an RLS server can act as both an LRC and RLI server.

Functions are divided into the following groups:

- [Activation](#)
- [Connection Management](#)
- [Operations on an LRC server](#)
- [Operations on an RLI server](#)
- [Miscellaneous Types and Functions](#)
- [Query Results](#)
- [Status Codes](#)

Applications using this API should include **globus\_rls\_client.h**, and be linked with the library **globus\_rls\_client - FLAVOR**.

### 5.1.1 Detailed Description

All of the functions in the API that return status return it in a `globus_result_t` structure.

Prior to version 2.0.0 an integer status was returned. The `globus_result_t` structure includes an integer "type" which is set to one of the status codes defined below (the same values that were returned by earlier versions of the API). The function [globus\\_rls\\_client\\_error\\_info\(\)](#) may be used to extract the status code and/or error message from a `globus_result_t`. `GLOBUS_SUCCESS` is returned when the operation was successful.

#### Return values:

*conf\_list* List of configuration options.

*GLOBUS\_SUCCESS* List of retrieved config options returned in *conf\_list*, each datum is of type [globus\\_rls\\_string2\\_t](#). *conf\_list* should be freed with [globus\\_rls\\_client\\_free\\_list\(\)](#). There may be multiple "acl" entries in the list, since the access control list can include more than one entry. Each acl configuration value is consists of a regular expression (matched against grid-mapfile users or DNs), a colon, and space separated list of permissions the matching users are granted.

### 5.2.4.3 [globus\\_result\\_t](#) [globus\\_rls\\_client\\_set\\_configuration](#) ([globus\\_rls\\_handle\\_t](#) \* *h*, char \* *option*, char \* *value*)

Map attribute value to string.

**Parameters:**

*attr* Attribute to convert. If *attr->type* is `globus_qls_attr_type_date` then the resulting string will be in the format MySQL uses by default, which is YYYYMMDDHHMMSS.

*buf* Buffer to write string value to. Note if *attr->type* is `globus_qls_attr_type_str` then *attr->val.s* is returned, and *buf* is unused.

*buflen* Size of *buf* in bytes.

**Return values:**

*String Value* Attribute value converted to a string.

**5.2.4.6** `globus_result_t globus_qls_client_s2attr (globus_qls_attr_type_t type, char * sval, globus_qls_attribute_t * attr)`

##### Parameters:

- r* Result returned by RLS API function. *r* is freed by this call and should not be referenced again. If *preserve* is set then a new `globus_result_t` is constructed with the same values and returned as the function value.
- rc* Address to store error code at. If NULL error code is not returned.
- buf* Address to store error message at. If NULL error message is not returned.
- preserve* If GLOBUS\_TRUE then a new `globus_result_t` is constructed with the same values as the old and returned as the function value.
- buflen* Size of *buf*.

##### Return values:

- globus\_result\_t* If *preserve* is set a new `globus_result_t` identical to *r* is returned, otherwise GLOBUS\_SUCCESS.

#### 5.2.4.8 `int globus_list_len (globus_list_t * len)`

Compute length of list.

`globus_list_size()` is implemented using recursion, besides being inefficient it can run out of stack space when the list is large.

#### 5.2.4.9 `char* globus_rls_errmsg (int rc, char * specificmsg, char * buf, int buflen)`

Map RLS status code to error string.

##### Parameters:

- buf* Buffer to write error message to.
- buflen* Length of *buf*. Message will be truncated to fit if too long.

##### Return values:

- char* \* Returns *buf*, error message written to *buf*.

## 5.3 Query Results

List results are returned as `globus_list_t`'s, list datums depend on the type of query (eg [globus\\_rls\\_string2\\_t](#), [globus\\_rls\\_attribute\\_t](#), etc).

### Data Structures

- struct [globus\\_rls\\_attribute\\_object\\_t](#)  
*globus\_rls\_client\_lrc\_attr\_search()* returns a list of these structures which include the object name (LFN or PFN) and attribute value found by the query.
- struct [globus\\_rls\\_string2\\_t](#)  
String pair result.
- struct [globus\\_rls\\_string2\\_bulk\\_t](#)  
String pair result with return code, returned by bulk query operations.

## Functions

- `globus_result_t globus_rls_client_free_list (globus_list_t *list)`

### 5.3.1 Detailed Description

List results are returned as `globus_list_t`'s, list datums depend on the type of query (eg `globus_rls_string2_t`, `globus_rls_attribute_t`, etc).

A list result should be freed with `globus_rls_client_free_list()` when it's no longer needed. RLS supports limiting the number of results returned by a single query using an offset and reslimit. The offset specifies which result to begin with, reslimit specifies how many results to return. Offset should begin at 0 to retrieve all records. If reslimit is 0 then all results are returned at once, unless the server has a limit on results configured. If NULL is passed as the offset argument then the API will repeatedly call the query function until are results are retrieved. The following are equivalent examples of how to print the lfn,pfn pairs returned by `globus_rls_client_lrc_get_lfn()`:

```
globus_list_t *str2_list;
globus_list_t *p;
globus_rls_string2_t *str2;

// Retrieve all results, API will handle looping through partial results
// if the server has a limit configured. Error handling has been omitted.
globus_rls_client_lrc_get_lfn(h, "somepfn", NULL, 0, &str2_list);
for (p = str2_list; p; p = globus_list_rest(p)) {
    str2 = (globus_rls_string2_t *) globus_list_first(p);
    printf("lfn: %s pfn:%s\n", str2->s1, str2->s2);
}
globus_rls_client_free_list(str2_list);

// This code fragment retrieves results 5 at a time. Note offset is set
// to -1 when the server has no more results to return.
int offset = 0;

while (globus_rls_client_lrc_get_lfn(h, "somepfn", &offset, 5, &str2_list) == GLOBUS_SUCCESS) {
    for (p = str2_list; p; p = globus_list_rest(p)) {
        str2 = (globus_rls_string2_t *) globus_list_first(p);
        printf("lfn: %s pfn:%s\n", str2->s1, str2->s2);
    }
    globus_rls_client_free_list(str2_list);
    if (offset == -1)
        break;
}
```

### 5.3.2 Function Documentation

#### 5.3.2.1 `globus_result_t globus_rls_client_free_list (globus_list_t * list)`

##### Parameters:

*list* List returned by one of the query functions.

##### Return values:

**GLOBUS\_SUCCESS** List and contents successfully freed.
